Abstract

Equality of gender is the 5th objective of sustainable development in United Nations¹.

This equality can be reached working on measure and analyze data and to apply politics from the results. On many gender studies, we need to count males and females deciding gender from names, for instance, research papers, job positions, streets, ... The traditional way is to use commercial APIs with proprietary data without idea about how the data has been built. Another way, is taking data from wikipedia or scientific sites.

With Open Data idea, many statistics institutions are providing Open Datasets about name, gender and frequency. So, we need a scientific discussion about unifying formats, make easy ways to process these data and ways towards make standards. In this discussion, we take into account minorities, for example, LGTB claims such as attending the non binary reality.

The dataset is covering more than 20 countries in the occidental world. Having more names than any open source software in this moment. Allowing to measure gender gap to students and academics interested on the phenomenon.

There are a warranty of quality on reproducible research the citation about official sources provided by statistics institutions

making easy the peer review and opening doors to the semantic web and the attention to minorities such as trans gender people, or cultures with own languages in states with another main language doing more cheaper to measure the gender gap.

1 Introduction

Nowadays, many people is using APIs such as Genderapi, Genderize, Namsor, or NameApi. Another people is using solutions based on Wikipedia `*****CITAR*****`, or free software solutions (NLTK, R Gender, Gender Detector, Gender Code, ...) with few number of names due to use files of a single country or being software not maintained in the long time. Wikipedia is not taking into account the frequency of the names.

However, the gender gap is a problem recognised in United Nations and the IT market is leading big inequalities in the world in economy and gender gap. This paper present a real work collecting data with a scientific perspective to solve the problem.

Another previous work [KWL⁺16] about this kind of tools is discussing about the datasets as a way to improve the accuracies, comparing tools that is using different public datasets (SSA, IPUMS, Sexmachine, ...)

We are facing the solution by the practical way augmenting the number of names using official statistics and taking into account diversity goals such as non binary gender and cultural minorities.

The remainder of this paper is structured as follows:

In Section 2 we discuss the different ways to find evidence about names, gender and frequency.

Section 3 introduces the diversity discussion about minorities (cultural, LGTB, ...)

Section 4 is giving clues about how to approach the semantic web goals with the previous dicussion presented.

¹<https://www.un.org/sustainabledevelopment/gender-equality/>

Section 5 reports on values of accuracy and offers a confusion matrix using a scientific dataset.

Section 6 is about how we use Machine Learning in **damegender**.

Section 7 discusses limitations and further research, and concludes the paper.

2 Truehood and Falsehood in names, gender and frequency

The current idea in the field is the data about name, gender and frequency is ok because there are people who is paying by it, or many people is downloading a product. This intuition is right generally, although sometimes the people is paying by a bad product due to a good marketing strategy, a monopoly or there are a fraud, ... Another idea is the people trust in the government about statistics such as economy, demography, democracy, ... So the people can trust on names, gender and frequency. In Damegender, we are trusting in both notions about truehood: the market's point of view and the official statistics's point of view.

Sometimes there are problems downloading the official statistics but there are people who has retrieved these data, for example, with webscraping. We want classify these files with another idea about truehood.

Another problem arises when the government does little chances in the data, sometimes communicating it to the users and another times not. That could be a problem about upgrades, but it's not a problem with the truehood, although it's possible make a trace about this chances.

Another sources to retrieve gender and names can be personal scientific websites, wikipedia, or similar, but these sources is not giving the frequency, now. So, we are rejecting this idea.

With an international free dataset about names, gender and frequency we can build reproducible science in fields such as Natural Language Processing (gender detection from the name), social sciences (gender gap [HSFH18, MLA⁺11]), linguistic [LN05, Kru62, vdWRvdW⁺20], software engineering [VCS12], ...

3 Gender, Language, Nation and Diversity

The first intuition about gender is male or female, but there non binary options about gender such as transgender that is changing laws in the governments, so in some states a person can be registered as non male and non female. There are Open Datasets not provided by states about names classified as transgender. A good option is to wait the updates in laws and releases in open datasets with these non binary ideas. Meanwhile,

it's possible to give to the users software to understand how many males and females is using a name.

Exists rules and exceptions in the languages to predict if a name is about male or female when you don't know the name. For example, in spanish or english there are more names ending with 'a' classified as females than classified as males. And Andrea is female in Spain and male in Italy. So, it's useful to understand the language and culture associated with a name. Language is close to nation, but there are differences, for example, in Spain there are several languages basque, catalan, castillian, ... or the spanish is the main language in Spain and in another countries such as Argentina, Mexico, Ecuador, Bolivia, ... So, it would be useful to detect the language and nation from names and surnames to help to detect gender.

Some countries, such as Spain, are providing free datasets about surnames but we need more efforts from many countries on this objective. On other hand, there are previous works to relate name and surnames with ethnicity using Wikipedia and Machine Learning.

4 Semantic Web

When we are describing people with names and gender could be giving semantic richness with semantic markup taking into account the lessons learned about the domain, for example, using microformats. Changing the current situation using a poor html:

```
<table class="infobox" style="width:22.7em;
line-height: 1.4em; text-align:left;
padding:.23em;">
  <tbody>
    <tr><th colspan="3" class="cabecera"
style="text-align:center;color:black;">
      Juan</th></tr><tr>
[...]
```

Juan		
[...]		
scope="row"		
Género		
Masculino		

Towards the semantic way:

```
<div class="h-card">
  <span class="p-name">Emma Goldman</span>
  <span class="p-gender p-gender-female
p-gender-female-us
p-gender-female-inter">
    Female
  </span>
  <span class="p-street-address">
    123 Main St
  </span>
```

Dataset	SSA	namdict	NLTK	Damegender
males	91.320	48.821	9999999999	256.320
females	91.320	48.821	9999999999	278.914

Table 1: Comparison about the number of names

```
<span class="p-locality">Some Town</span>
<span class="p-region">CA</span>
<span class="p-postal-code">90210</span>
</div>
```

With a richness markup take into account the gender in the context of a country.

5 Damegender Open Datasets Collection

In Damegender, we have unified the different formats to name, gender and frequency from official sources in these countries: Austria, Australia, Belgium, Canada, Denmark, Germany, Spain, Finland, France, Great Britain, Ireland, Mexico, New Zealand, Portugal and Slovenia.

Later, we have merged these datasets building a free and international dataset.

Generally, these data are providing name, gender and frequency about births (Canada), although in some countries (Spain) are giving the total.

We have found open datasets about countries such as Turkey and China retrieved by another open source developers that is being included in Damegender, but not in the international dataset. In Turkey the data has been retrieved using webscraping. And in China the data has been built by a company in collaboration with the China government and contributed to R language program. We want compare precision about this dataset with the commercial solutions to understand the truthhood about these datasets.

When the work is finished, we could to rebuild machine learning models to predict new names and nicknames in any language and culture. The results is the longest list of public names.

6 Measuring Gender Gap. GNU/Linux as Use Case

With a trust open dataset about names, gender and frequency is too easy to measure gender gap. Doing cheap to measure gender gap more students and academic people could work in the fifth Objective Development Sustainable of United Nations: to delete the gender gap.

This section is divided counting males and females in Debian, GNU and Linux.

We have reached the csv files from different ways to know the names about the people in these communities.

When this paper was being wrote in the Debian community all members must be collaborating with a gpg key, so we can count males and females from the keyring. The keyring was imported with gpg commands and later was dumped the keyring in a csv file.

In the moment to write this paper GNU² and Linux³ has websites with the people collaborating in these projects. So, making webscraping scripts we have downloaded the people and processed the people to csv files

In Damegender, we have developed csv2gender, a software with a csv file as input and deploy a statistics graph and/or return the result of males, females and unknowns about the input.

To make easy to reproduce the experiment we are pasting the commands used with the version 0.3.4 of damegender.

```
python3 csv2gender.py files/gnu-maintainers.csv
--first_name_position=0
--title="GNU maintainers grouped by gender"
--dataset="inter"
--outcsv="files/gnu-maintainers.gender.csv"
--outing="files/gnu-maintainers.gender.png"
--noshw --delete_duplicated
```

```
python3 csv2gender.py files/linux-maintainers.csv
--first_name_position=0
--title="Linux maintainers grouped by gender"
--dataset="inter"
--outcsv="files/linux-maintainers.gender.csv"
--outing="files/linux-maintainers.gender.png"
--noshw --delete_duplicated
```

```
python3 csv2gender.py files/debian-maintainers.csv
--first_name_position=0
--title="Debian maintainers grouped by gender"
--dataset="inter"
--outcsv="files/debian-maintainers.gender.csv"
--outing="files/debian-maintainers.gender.png"
--noshw --delete_duplicated
```

The inter dataset was created merging several open datasets downloaded from official statistics sites from different nations: Austria, Australia, Belgium, Canada, Germany, Denmark, Spain, Finland, Ireland, Iceland, Mexico, New Zealand, Portugal, Slovenia, United States of America, Uruguay and France. That's a good representation of the Western World and the Free Software world is populating this world's area

²<https://www.gnu.org/people/>

³<https://www.kernel.org/doc/html/latest/process/maintainers>

Linux divides the developers in 537 males (73.9%), 98 females (13.5%) and 92 unknowns (12.7%). The number of unknowns is due to different reasons, but it's so common in Linux that the developer is a company and not a name of a person.

Debian divides the developers in 408 males (75%), 69 females (12.7%) and 67 unknowns (12.3%).

GNU divides the developers in 164 males (89.6%), 12 females (6.6%) and 7 unknowns (3.8%)

The GNU people has a number lowest in females, they are the founder of the Free Software philosophy, the Debian principles and the Open Source philosophy was invented later influenced by GNU with very similar practical decisions (for example: deciding licenses for the software). Richard Stallman returned to be president recently apologizing by his personal behaviour with the females.⁴

7 Conclusions

discusses limitations and further research, and concludes the paper.
